8 Further phytochemical investigation into the aerial parts of *Achillea clavennae* has resulted in the
9 isolation of three new sesquiterpene lactones: two highly oxygenated germacranolides (**1**, **2**) and
10 the *iso-seco*-guaianolide, 9(*R*)-acetoxy-3-*O*-methyl-*iso-seco*-tanapartholide (**3**). Eight known
11 compounds were also found in this plant species, of which 9 α -acetoxyanin (**5**), sintenin (**6**) and
12 oleanolic acid (**7**) were detected for the first time. The structures of the isolated compounds were
13 elucidated by combined spectroscopic methods (1D and 2D NMR, HRESIMS, CIMS, FTIR).
14 While the predominant metabolite germacranolide sintenin (**6**) was not cytotoxic, the new *iso*-
15 *seco*-guaianolide (**3**) displayed cytotoxicity comparable to that of cisplatin and the lactone
16 apressin (**4**), inducing partly apoptotic death in human U251 and rat C6 glioma cell lines.

15 **Key words:** *Achillea clavennae* L. (Asteraceae), sesquiterpene lactones, *iso-seco*-guaianolide,
16 NMR, cytotoxicity, apoptosis

1 Introduction

2
3
4
5
6
7
8 The genus *Achillea* L. contains over 100 species, mainly distributed in Europe and the temperate
9
10 areas of Asia [1]. Hitherto, about sixty *Achillea* species have been phytochemically investigated,
11
12 but far fewer have been biologically tested [2-3]. The composition and antibacterial activities of
13
14 the essential oils have been examined the most, even many times for same species, as in the case
15
16 of *A. millefolium*, the most popular and wide-spread species of the genus. Alkamides from the
17
18 roots were studied in detail, as compounds initially considered relevant for chemotaxonomy.
19
20 Nowadays, the leaf exudates (mainly containing flavonoid aglycons) are most frequently
21
22 analyzed for this purpose. The main constituents of the investigated plant extracts are terpenoids
23
24 (largely sesquiterpene lactones) and flavonoids, classes of compounds with documented
25
26 biological activity [2-3]. This fact, as well as the use of many *Achillea* species in traditional
27
28 medicine worldwide (for their anti-inflammatory, antispasmodic, stomachic, digestive,
29
30 cholagogue, antipyretic, emmenagogue, hemostatic, hypotensive, diuretic and urinary antiseptic
31
32 activities), makes this genus interesting for extensive examination.
33
34
35
36
37

38
39 *Achillea clavennae*, which is the subject of the present study, grows on the elevated carbonate
40
41 rocks of the eastern and southern Alps, as well as on mountains in the western part of the Balkan
42
43 Peninsula (at altitudes between 1500 and 2500 m). According to the morphological characters
44
45 and flavonoid profiles, *A. clavennae* belongs to the group of alpine species (the subgroup *A.*
46
47 *moschata*) of the section *Ptarmica* (Mill.) W.D.J. [4]. This species was discovered and described
48
49 as a healing plant (cholagogue, stomachic and anthelmintic) at the beginning of the 17th century
50
51 [5]. At present, it is used in Croatian folk medicine to treat abdominal pain, the common cold,
52
53 influenza and respiratory disorders [6]. Examination of the essential oil of *A. clavennae* from this
54
55 locality verified its high antibacterial activity against some respiratory tract pathogens [6-7]. The
56
57
58
59
60

1 extract of a plant collection from Macedonia (containing alkanes, fatty acids, monoterpenes,
2 guaiane sesquiterpenes and flavonoids) also exhibited a wide range of antimicrobial activities [8].
3 Our previous study of the aerial parts of *A. clavennae* from Montenegro (the Komovi Mountain)
4 revealed that guaianolides, bisabolenes and flavonoids were its main constituents. Subsequent
5 work, which was the first assessment of the biological activity of *A. clavennae* constituents,
6 revealed a remarkably high cytotoxic activity of the lactones 9 α -acetoxyartecanin and apressin
7 [9].

8 In the present study, the aerial parts of this alpine species from the Prokletije Mountains
9 (Montenegro) were analyzed. Three new sesquiterpene lactones (**1-3**) and eight known
10 compounds (apressin (**4**), 9 α -acetoxyanin (**5**), sintenin (**6**), oleanolic acid (**7**), chrysetunone, 11-
11 dehydroxy,11-hydroperoxyindicumenone, sesamin, centaureidin) were isolated and structurally
12 determined. In addition, the *in vitro* cytotoxic activity of the predominant lactones **3**, **4** and **6** was
13 examined.

15 Results and Discussion

17 Fractionation of the crude extract (petrol-Et₂O-MeOH, 1:1:1) of the air-dried aerial parts of the
18 title plant, by repeated silica gel column chromatography and preparative TLC, gave six
19 sesquiterpene lactones (new lactones **1-3**, apressin (**4**) [10], 9 α -acetoxyanin (**5**) [11] and sintenin
20 (**6**) [12]), two bisabolenes (chrysetunone [13] and 11-dehydroxy,11-hydroperoxyindicumenone
21 [9]), lignan sesamin [14], flavonol centaureidin [15], and oleanolic acid (**7**) [16] (**Fig. 1**).
22 Apressin (**4**), chrysetunone, 11-dehydroxy,11-hydroperoxyindicumenone, sesamin and
23 centaureidin had already been identified in the aerial parts of *A. clavennae* [9], but compounds **5**,

1 **6**, and **7** were found for the first time in this plant species. Oleanolic acid, atypical for the genus
2 *Achillea*, had previously been reported only in *A. teretifolia* [17]. Bisabolene derivatives also
3 rarely occur in this genus (*A. odorata* [18], *A. cretica* [19] and *A. clavennae* [9]), especially
4 hydroperoxy-bisabolenes, previously found only in *A. clavennae*.

6 **Fig. 1**

7
8 The molecular formula $C_{19}H_{24}O_8$, for the lactone **1**, was deduced from the positive-ion mode
9 HRESIMS (m/z 381.15398 $[M+H]^+$; calc. 381.15439). The CI mass spectrum showed the
10 pseudomolecular ion, $[MH-O_2]^+$ (m/z 349), $[MH-O_2-HOAc]^+$ (m/z 289) and $[MH-2HOAc]^+$ (m/z
11 261) ions, indicating the presence of the hydroperoxy and two acetoxy groups. The
12 germacranolide core of **1**, with **C-4** and C-10(**14**) double bonds, α -methylene- γ -lactone group and
13 the substitution at C-1, C-3 and C-9, was recognized in 1H NMR spectrum (**Table 1**). Singlets at
14 δ 2.03 and δ 2.08, and broad singlet at δ 8.75 originated from two OAc and HOO groups,
15 respectively. Low-field signals at δ 5.33 *dd* ($J_1 = 5.0$ Hz, $J_2 = 11.5$ Hz), δ 5.14 *brd* ($J = 10.5$ Hz)
16 and δ 4.24 *brd* ($J = 10.0$ Hz) belonged to their geminal protons: H-3, H-9 and H-1. H-3 was
17 distinguished on the basis of HMBC correlations H-3(δ 5.33)/C-5 and H₃-15/C-3(δ 75.6).
18 Carbons at δ 76.8 and δ 86.1, connected in the HSQC spectrum with protons at δ 5.14 and δ 4.24,
19 respectively, showed HMBC correlations with H₂-14, which only proves C-9 and C-1 positions
20 of remaining substituents. Other significant HMBC correlations regarding the arrangement of this
21 part of molecule were missing. Taking into account the presence of the lactone santonin in this
22 plant sample (biogenetically related to **1**), and COSY and NOESY correlations (**Fig. 2**) of the
23 proton geminal to OAc (δ 5.14), as well as of H geminal to OOH (δ 4.24), it was deduced that the

1 former proton is H-9 and the latter is H-1. Moreover, NOEs H-9/ H-7, H-8 α , H-1 and H-1/H-2 α ,
2 H-3, H-5 revealed α -position of these protons, hence β -position of all substituents. One more
3 high-frequency shifted *brd* ($J = 10.5$ Hz) at δ 5.45 was assigned to H-5 on the basis of HMBC
4 correlations H₃-15,H-3/C-5(122.2). Due to the lack of the important HMBC correlations,
5 coupling patterns in COSY spectrum and NOESY cross-peaks (**Fig. 2**) were crucial for
6 distinguishing CH₂-2 and CH₂-8 groups, as well as identifying α and β protons. NOEs H-6/H₃-15
7 and H₃-15/H-14' disclosed *syn*-orientation of Me-15 and CH₂-14 on the β -face of the trans-4-
8 cyclodecene. Such geometry affects spatial closeness of α -pseudo-axial protons H-1, H-3, H-5
9 and H-9, as well as of β -pseudo-axial H-2 with H-14' and Me-15, and also H-8 β with H-14 and
10 H-6, which was evidenced by corresponding NOE correlations (**Fig. 2**). Finally, **1** was identified
11 as 3 β ,9 β -diacetoxy-1 β -hydroperoxy-6 β ,7 α H-germacra-4,10(14),11(13)-trien-12,6 α -olide. Three
12 substituted $\Delta^{4,10(14)}$ -germacranolides have not previously been found in the genus *Achillea*.

14 Fig. 2

15
16 For lactone **2**, closely related to **1**, the structure was determined from the positive-ion mode
17 HRESIMS, CIMS, and ¹H NMR spectra. Prior to recording 2D NMR spectra, this compound was
18 decomposed in the NMR tube, therefore the stereochemical data were obscured. According to
19 [M+H]⁺ ion at m/z 367.17513 (calc. 367.17485) in HRESIMS the molecular formula C₁₉H₂₆O₇
20 was established. CI mass spectrum contained [MH-HOAc]⁺ (m/z 307), [MH-HOAc-H₂O]⁺ (m/z
21 289) and [MH-2HOAc]⁺ (m/z 247) ions, implying the existence of a hydroxy group (instead of
22 hydroperoxy in comparison with **1**) and two acetoxy groups in the molecule. The similarity of the
23 ¹H NMR data of **2** (Table 1) to that of **1** indicated the same basic structure. ¹H NMR spectrum of

1
2
3 1 **2** exhibited signals of two acetoxy groups (δ 2.03 *s* and δ 2.08 *s*, respectively) and their geminal
4
5
6 2 protons at δ 5.29 *dd* ($J_1 = 5.0$ Hz, $J_2 = 11.4$ Hz, H-3) and δ 5.10 *brdd* ($J_1 = 3.2$ Hz, $J_2 = 7.6$ Hz, H-
7
8 9). Signals of H-5 (δ 5.39 *brd*, $J = 10.4$ Hz), Me-15 (δ 1.58 *d*, $J = 1.6$ Hz), H-14 (δ 5.56 *brs*) and
9
10 H-14' (δ 5.48 *brs*) documented double bonds Δ^4 and $\Delta^{10(14)}$, respectively. Broad doublet at δ 4.16
11
12 ($J = 9.8$ Hz) originated from H-1, which is geminal to the hydroxy group. Missing the
13
14 5 characteristic low-field H-13 and H-13' doublets of the exomethylene group, as well as *brs* of the
15
16 6 hydroperoxy group, and the appearance of quintet of H-11 (δ 2.74, $J = 7.6$ Hz) and doublet of
17
18 7 Me-13 (δ 1.19, $J = 7.6$ Hz) were the main distinctions of ^1H NMR spectrum of **2**, in comparison
19
20 8 with **1**. It is very possible that the lactone **2** (3,9-diacetoxy-1-hydroxy-6 β ,7 α ,11H-germacra-
21
22 9 4,10(14)-dien-12,6 α -olide) was formed from sintenin, via corresponding 1,10-epoxy derivative.
23
24 10 The hydroperoxide **1** and sintenin might have the same precursor, most probably costunolide or
25
26 11 corresponding mono- or di-acetoxy derivative.

14 **Table 1**

16 Molecular formula $\text{C}_{18}\text{H}_{22}\text{O}_7$ for lactone **3** was concluded from HRESI mass spectrum, recorded
17 in the positive-ion mode, using ammonium formate for the ionisation ($[\text{M}+\text{NH}_4]^+$ at m/z
18 368.17165, calc. 368.17038; $[\text{M}+\text{Na}]^+$ at m/z 373.12752, calc. 373.12577). In EI mass spectrum,
19 ions $[\text{M}]^+$ (m/z 350), $[\text{MH}-\text{HOAc}]^+$ (m/z 290) and $[\text{MeC}=\text{O}]^+$ (m/z 43) were discerned, which
20 implied the presence of an acetoxy group and the methyl ketone group. The IR spectrum revealed
21 four carbonyls with absorption bands at 1765 cm^{-1} (γ -lactone), 1749 cm^{-1} (OAc), 1733 cm^{-1}
22 ($\text{C}=\text{O}$) and 1708 cm^{-1} ($\text{C}=\text{O}$). In the ^1H NMR spectrum (**Table 1**) characteristic doublets for α -
23 methylene- γ -lactone group (H-13: δ 6.40, $J = 2.6$ Hz; H-13': δ 5.67, $J = 2.0$ Hz) and a multiplet

1 of H-7 (δ 3.19) were present. These protons, coupled with each other, were a part of one of the
2 two spin systems recognized in TOCSY spectrum (**Fig. 3**). Besides H₂-13 and H-7, this system
3 included H-6 (δ 5.06 *d*, J = 4.6 Hz), H₂-8 (δ 2.09 *t*, J = 7.0 Hz) and H-9 (δ 5.13 *t*, J = 6.8 Hz), a
4 low-field proton geminal to an acetoxy group. A singlet of OAc was partly overlapped (δ 2.15-
5 2.17) with singlets of two methyl groups bound to sp²-carbons. One of these signals was assigned
6 to Me-14 at carbonyl C-10 and the other to Me-15 at olefinic C-4 (double bound to C-5). The
7 multiplicity of H-6 indicated C-5 to be quaternary. These data, together with the evidence about
8 the existence of separated ABX spin system of five-membered ring, indicated *iso-seco*-
9 guaianolide structure of **3**. ABX system was constituted of diastereotopic CH₂-2 group (A: δ 2.70
10 *dd* (J_1 = 6.2 Hz, J_2 = 18.4 Hz), B: δ 2.34 *dd* (J_1 = 2.2 Hz, J_2 = 18.4 Hz)) and a proton H-3 (X: δ
11 4.31 *brd* (J = 4.8 Hz)) geminal to OMe group (δ 3.42 *s*). Therefore, **3** is 9-acetoxy-3-*O*-methyl-
12 *iso-seco*-tanaparholide. In NOESY spectrum, more or less expected correlations which confirm
13 the former structure appeared: H₂-8/H-13', H-9, H-6, OAc, H-7; H-2/H-2', H-3, OMe; H-2'/H-2,
14 H-3; H-7/H-13', H-6. Because of the remote nature of the C-3 stereocenter and the flexibility of
15 the (C-8)-(C10) fragment, there was not an evidence about stereochemistry at C-3 and C-9. The
16 configuration at C-9 was deduced on the basis of the previous findings that *seco*-guaianolides,
17 *endo*-peroxyguaianolides and bis-epoxy-guaianolides were biosynthetically related: all derived from
18 common cyclopentadiene precursors; *seco*- and *iso-seco*-guaianolides formed by a cleavage of
19 (C-1)-(C-10) bond of corresponding epoxy-guaianolides [20]. Accordingly, 9(*R*)-configuration of
20 **3** is proposed, as compatible with 9 α -position of acetoxy group of presented endoperoxide **4** and
21 bis-epoxide **5**.

22 *Seco*-guaianolides and *iso-seco*-guaianolides mainly occurred in the genera *Artemisia*, *Tanacetum*
23 and *Achillea*. *Iso-seco*-tanaparholide, firstly isolated from *Artemisia rutifolia* in 1986 [21], has

1 recently been identified in *Tanacetum parthenium*, together with its 3-epimer (3α -OH), and
2 afterwards both were synthesized. A little difference in NMR data of two epimers and unequal
3 optical rotations were exploited for the comprehensive stereochemical revision of previously
4 isolated 'iso-seco-tanaparthalides' from different plants [22]. *Epi-iso-seco-tanaparthalide* was
5 recognized as a major product in some *Achillea* species.

6 Reviewing literature for 3-epimers of 3-*O*-methyl-iso-seco-tanaparthalides we could not find
7 strong evidence for its distinction [11, 23, 24]. Therefore, we gave up resolving C-3 configuration
8 on the basis of comparing our data with existing spectroscopic data. As well as in the case of iso-
9 seco-tanaparthalides, synthesis of these epimeric compounds is essential for their complete
10 characterization and also required for a revision of the preceding literature data.

12 Fig. 3

14 The guianolide **5** was easily determined as 9α -acetoxycanin due to the similarity of its spectral
15 data with those of the previously isolated diastereomer 9α -acetoxycartecanin from the same plant
16 [9]. 9α -Acetoxycanin was also found in *A. depressa* [11]. In the previous study of 1D and 2D
17 NMR data of eleven 1,2-epoxy- and 1,2:3,4-diepoxy-guianolides, which we had isolated from
18 different *Achillea* species, we noted a relation between the chemical shifts of C(H)-5 fragment
19 and the configuration of the 1,2-epoxy ring [25]. Briefly, a signal of H-5 (vicinal to the epoxide)
20 of $1\alpha,2\alpha$ -epoxyguaianolides is shielded, while C-5 is deshielded in comparison with
21 corresponding data of appropriate β -epoxy-diastereomers. Here, signals of H-5 and C-5 of **5**
22 appeared at δ 2.65 and δ 50.6, respectively, while the signals of its *bis*- β -epoxy-diastereomer 9α -

1 acetoxyartecanin were noticed at δ_{H} 2.87 and δ_{C} 43.0 [9], which is one more confirmation of the
2 mentioned, previously recognized spectral rule for this type of compounds.

3
4 For testing the *in vitro* cytotoxicity of *A. clavennae* sesquiterpenoids, we have selected the
5 predominant metabolite germacranolide sintenin (**6**), lactone apressin (**4**) and the new *iso-seco*-
6 guaianolide (**3**). The glioma cell lines C6 and U251 were chosen as targets, having in mind that
7 gliomas, the most common primary malignancy of the central nervous system, are extremely
8 aggressive and mostly incurable tumors [26]. The treatment with compound **6** for 24 h had no
9 significant influence on either mitochondrial respiration or numbers of glioma cells (Fig. 4),
10 which is consistent with previous results obtained in various cancer cell lines [27, 28]. Compound
11 **4** was toxic to all tested cells, including primary astrocytes (Fig. 4), which is in accordance with
12 the earlier reports [9]. The new *iso-seco*-guaianolide (**3**) also displayed a significant dose-
13 dependent cytotoxicity towards glioma cells, as determined both by MTT assay for mitochondrial
14 respiration and crystal violet test for cell numbers (Fig. 4). The analysis of the IC_{50} values
15 presented in **Table 2** indicates that compound **3** was significantly more active against glioma
16 cells than compound **4**, but somewhat less efficient than the prototypical anticancer drug
17 **cisplatin**. Importantly, unlike compound **4** and cisplatin, compound **3** displayed only a limited
18 toxicity towards rat primary astrocytes (Fig. 4). While this could be due to a lower proliferation
19 rate of primary astrocytes, it nevertheless indicates that transformed glial cells might be more
20 selective to compound **3** than their primary counterparts.

21
22 **Fig. 4**

23 **Table 2**

1
2
3 1
4
5 2 After confirming the *in vitro* antiglioma action of compound **3**, we next assessed its ability to
6
7 3 induce programmed cell death known as apoptosis. We first examined activation of caspases, the
8
9 4 main apoptosis-executing enzymes [29], using fluorescent-labeled pan-caspase inhibitor ApoStat
10
11 5 (Fig. 5A). Flow cytometric analysis revealed that compound **3** induced a dose- dependent caspase
12
13 6 activation in both C6 and U251 glioma cells. Furthermore, the cell cycle analysis after PI staining
14
15 7 of cellular DNA demonstrated that the exposure to compound **3** increased the numbers of
16
17 8 hypodiploid glioma cells with fragmented DNA (sub-G0/G1 compartment) (Fig. 5B), which is a
18
19 9 hallmark of apoptosis [30]. Annexin-detectable externalization of phosphatidylserine is another
20
21 10 apoptotic marker [31], and the treatment with compound **3** increased the numbers of annexin⁺
22
23 11 glioma cells displaying phosphatidylserine in the outer leaflet of cell membrane (Fig. 5C). The
24
25 12 effects of compound **3** (25 μM) on DNA fragmentation (21.5% hypodiploid cells) and
26
27 13 phosphatidylserine exposure (32.8% annexin⁺ cells) in U251 cells were only slightly less
28
29 14 prominent than those of cisplatin at the same concentration (32.4% and 37.8%, respectively; data
30
31 15 not shown). These results clearly demonstrate that compound **3** induces apoptotic death of glioma
32
33 16 cells. However, it should be noted that compound **3** also increased the proportion of PI⁺ cells with
34
35 17 the cell membrane damage (Fig. 5C), which could be late apoptotic and/or necrotic cells.
36
37 18 Therefore, the possibility that compound **3** could actually induce mixed apoptotic/necrotic death
38
39 19 requires further investigation.

Fig. 5

23 Oxidative-stress mediated mitochondrial dysfunction can lead to activation of caspases and
24 subsequent apoptotic cell demise [31]. Thus, we next examined the effects of compound **3** on

1 ROS production and mitochondrial membrane potential in glioma cells. The flow cytometric
2 analysis of cells stained with the redox-sensitive dye DHR demonstrated that compound **3** was
3 able to induce a dose- dependent ROS generation in glioma cell lines (Fig. 6A). The induction of
4 oxidative stress in compound **3**-treated C6 glioma cells was associated with the mitochondrial
5 membrane depolarization, as confirmed by the increase in green-to-red fluorescence ratio
6 (FL1/FL2) of the mitochondria-binding dye DePsipher (Fig. 6B). While these data indicate that
7 oxidative stress and subsequent mitochondrial depolarization are involved in the cytotoxicity of
8 compound **3**, this assumption remains to be directly confirmed.

10 Fig. 6

11
12 The previously isolated structurally related *iso-seco*-guaianolides were found to reduce viability
13 of immortalized human keratinocytes [32] and inhibit nitric oxide synthesis in
14 lipopolysaccharide-activated RAW 264.7 cells [33], probably through interaction with NF- κ B
15 signaling pathway [22]. The high biological activities of these compounds, including new *iso*-
16 *seco*-guaianolide **3**, are most likely connected with their α,β -unsaturated carbonyl electrophilic
17 groups: an α -methylene- γ -lactone and an α,β -unsaturated cyclopentenone. These groups are
18 known to mediate a Michael-type addition reaction with thiol-containing enzymes and proteins.
19 The importance of these structural features is primarily supported by the fact that lactone **6**
20 (without mentioned groups) was inactive in the present study. Accordingly, lactone **4** with only
21 one α,β -unsaturated carbonyl group was less active than **3**.
22 Taken together, our data for the first time demonstrate that compound **3**, a novel *iso-seco*-
23 tanaparholide from *A. clavennae*, triggers apoptotic death of glioma cells associated with the
24 induction of oxidative stress and mitochondrial depolarization.

6
7 3
8
9
10 4 *General experimental procedures*
11
12 5 Optical rotations were determined on a Rudolph Research Analytical automatic polarimeter,
13
14 6 Autopol IV. IR spectra were measured in the form of transparent films on a Perkin-Elmer FT-IR
15
16 7 spectrometer 1725X. ¹H and ¹³C NMR spectra were recorded on a Varian Gemini 2000 (at 200
17
18 8 and 50 MHz, respectively) and an Bruker Avance III spectrometer (at 500 and 125 MHz,
19
20 9 respectively) in CDCl₃, using TMS as internal standard. Mass spectra were obtained on a
21
22 10 Finnigan MAT 8230, BE DCI (150 eV, iso-butane). High-resolution LC/ESI TOF mass spectra
23
24 11 were measured on a HPLC instrument (Agilent 1200 Series) with a Zorbax Eclipse Plus C18
25
26 12 column (150 x 4.6 mm i.d.; 1.8 μm) and a diode-array detector (DAD) coupled with a 6210 time-
27
28 13 of-flight LC/MS system (Agilent Technologies). Elemental analysis was performed on a Vario
29
30 14 EL III C,H,N,S/O Elemental Analyzer (Elementar). CC was carried out on silica gel 60 (0.063-
31
32 15 0.200 mm, Merck). Preparative TLC was performed on silica gel G and F₂₅₄ (0.75 mm layer, 20 ×
33
34 16 20 cm). Silica gel 60 F₂₅₄ precoated aluminum sheets (0.25 mm, Merck) were used for TLC
35
36 17 control. Spots were detected under UV254 and by spraying with 50% H₂SO₄.

19 *Plant material*

46
47
48 20 The aerial parts of *Achillea clavennae* L. (Asteraceae) were collected at the flowering stage in
49
50 21 July 2002 in Montenegro at the mountain Prokletije (Karanfili, altitude ca. 2000 m). The plant
51
52 22 sample was identified by Prof. Pedja Janačković (Faculty of Biology, University of Belgrade,
53
54
55
56
57
58
59
60

1 Belgrade, Serbia), and a voucher specimen (BEOU16677) was deposited in the BEOU-
2 Herbarium, Institute of Botany, Faculty of Biology (Belgrade, Serbia).

3 4 *Extraction and isolation*

5 The air-dried aerial parts of *A. clavennae* (270 g) were extracted at a room temperature with a
6 mixture of petrol-Et₂O-MeOH (1:1:1, 2.1 L, 24 h) using the standard procedure [34]. The initial
7 extract (9.0 g) was treated with MeOH (3 × 50 mL) to yield 7.2 g of MeOH soluble portion.
8 Further fractionation was carried out on silica gel dry-column flash chromatography (250 g, 10 ×
9 14 cm), starting the elution with petrol (fraction **F1**, 400 mL) and increasing polarity by adding
10 Et₂O (20% to 100%, **F2-F10**, 350 mL each) and MeOH (15%, **F11**, 350 mL). Fractions were
11 evaporated, and **F7** (petrol-Et₂O 3:7, 423 mg) and **F8** (petrol-Et₂O 2:8, 441 mg) were combined
12 after inspection of analytical TLC (CH₂Cl₂-MeOH 97:3) and ¹H NMR spectra of all fractions.
13 **F6** (petrol-Et₂O 4:6, 558 mg) was chromatographed on silica gel CC (300 g, 45 × 3.5 cm;
14 CH₂Cl₂-MeOH 97:3) to yield 48 subfractions (~20 mL each). Fractions 7-12 (F6a, 62.4 mg), 22
15 (F6b, 24.1 mg), and 25-29 (F6c, 51.0 mg) were further purified by preparative TLC. **Sesamin (3.2**
16 **mg**, F6a/CH₂Cl₂-MeOH 97.5:2.5), **apressin (4, 3.5 mg**, F6b/CH₂Cl₂-MeOH 97:3) and **oleanolic**
17 **acid (7, 2.1 mg**, F6c/CH₂Cl₂-MeOH 97.5:2.5, repeated prep.TLC) were obtained.
18 **F7+8** (864 mg) was divided into 75 subfractions (~30 mL each) by silica gel CC (430 g, 70 × 3.5
19 cm) gradually increasing polarity of eluent (CH₂Cl₂-MeOH, 97.4:2.6 - 96:4). Subfr. F7a (23-26,
20 36.6 mg), F7b (27-33, 74.2 mg), F7c (34-49, 102.1 mg), F7d (54-57, 32.3 mg), and F7e (71-75,
21 56.2 mg) were purified by preparative TLC (always at several plates). Lactone **2** (1.1 mg) was
22 isolated from F7a and lactone **apresin (4, 10.9 mg)** from F7b with the same solvent system
23 (CH₂Cl₂-MeOH 96.5:3.5). Lactone **3** (5.4 mg) was obtained from F7c (CH₂Cl₂-MeOH 97:3). **11-**
24 **Dehydroxy,11-hydroperoxyindicumenone** (1.4 mg) was obtained from F7d together with

1 additional 1.1 mg of **3** (CH₂Cl₂-MeOH 96.5:2.5, repeated TLC). Chrysetunone (**0.5** mg) and
2 centaureidin (**1.4** mg) were isolated from F7e (CH₂Cl₂-MeOH 97:3).

3 Silica gel CC (300 g, 45 × 3.5 cm; CH₂Cl₂-MeOH 97:3) of **F9** (petrol-Et₂O 1:9, 495 mg) yielded
4 40 subfractions (~30 mL each), which were combined after analytical TLC. F9a (4-5, 37.5 mg)
5 yielded lactones **4** (8.5 mg), **1** (1.4 mg), and **6** (1.0 mg) after repeated preparative TLC (solvent
6 system CH₂Cl₂-MeOH 97:3). F9b (6-7, 28.2 mg) was washed out with Et₂O and an insoluble
7 portion was crystallized from CH₂Cl₂ giving 11.4 mg of sintenin (**6**). 9 α -Acetoxycanin (**5**, 0.9
8 mg) was isolated from F9c (13-16, 33.1 mg) after repeated preparative TLC with solvent systems
9 toluen-Et₂O-MeOH (7:2:1) and CH₂Cl₂-MeOH (97:3).

10 Lactone sintenin (10.0 mg) was also isolated from **F10** (Et₂O, 450 mg), which was firstly divided
11 into 20 subfractions (~30 mL each) by silica gel CC (280 g, 40 × 3.5 cm) using solvent system
12 CH₂Cl₂-MeOH (97:3). From combined fraction 4-8 (65.3 mg), this compound was separated as
13 insoluble in Et₂O.

11 61.60, H - 6.42; requires: C - 61.71, H - 6.33%.

13 *Cells and reagents*

14 All reagents were from Sigma-Aldrich (St. Louis, MO) unless stated otherwise. Human glioma
15 cell line U251 and rat glioma cell line C6 were kindly donated by Dr Pedro Tranque (Universidad
16 de Castilla-La Mancha, Albacete, Spain). The primary astrocytes were isolated from brains of
17 newborn Albino Oxford rats as previously described [35], in accordance with the ethical
18 guidelines stated in the "Principles of Laboratory Animal Care" (NIH publication #85-23, revised
19 in 1985). Tumor cell lines and primary rat astrocytes were grown in HEPES (20 mM)-buffered
20 RPMI 1640 cell culture medium, supplemented with 5% fetal bovine serum, 2 mM L-glutamine,
21 10 mM sodium pyruvate and 1% of antibiotic/antimycotic mixture at 37 °C in a humidified
22 atmosphere with 5% CO₂. The cells were prepared for experiments using trypsin/EDTA and
23 incubated in 96-well flat-bottom cell culture plates (2 × 10⁴ cells/well) for the cell viability

1
2
3 1 assessment, or 6-well plates (5×10^5 cells/well) for the flow cytometric analysis (plates were
4
5
6 2 from Sarstedt, Nümbrecht, Germany). Cells were rested for 24 h and then treated with
7
8 3 compounds **3**, **4** and **6**. Purity of **3**, **4** and **6** was confirmed by elemental analysis ($> 99\%$). Control
9
10 4 cultures were exposed to the corresponding amount of vehicle (DMSO). We observed no
11
12 5 influence of DMSO on any of the parameters tested (data not shown). Cisplatin ($\geq 99.9\%$,
13
14 6 Sigma-Aldrich), a well known anticancer drug was used in some experiments as a positive
15
16 7 control. Incubation times and concentrations of compounds are stated in figure legends.
17
18
19
20 8

21 22 9 *Cell viability*

23
24 10 Mitochondrial dehydrogenase activity, as an indicator of cell viability, was assessed by
25
26 11 mitochondria-dependent reduction of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium
27
28 12 bromide (MTT) to formazan, and the number of viable cells was determined using crystal violet
29
30 13 assay, exactly as previously described [36]. The MTT and crystal violet absorbance was
31
32 14 measured in an automated plate reader (Sunrise, Tecan, Dorstet, UK) at 570 nm. The IC_{50} values
33
34 15 were calculated using GraphPad Prism software.
35
36
37
38
39 16
40
41
42

43 44 17 *Caspase activation*

45
46 18 Activation of caspases was measured using cell-permeable FITC-conjugated pan-caspase
47
48 19 inhibitor ApoStat (R&D Systems, Minneapolis, MN), according to manufacturer's instructions.
49
50 20 The increase in green fluorescence (FL1) as a measure of caspase activity was detected using
51
52 21 FASCalibur flow cytometer (BD, Heidelberg, Germany). The results are presented as mean
53
54 22 intensity of ApoStat fluorescence.
55
56
57
58
59
60

23 24 24 *Apoptosis analysis*

1 DNA fragmentation as a marker of apoptotic cell death was analyzed by measuring the DNA
2 content of ethanol-fixed cells stained with DNA-binding dye propidium iodide (PI), exactly as
3 previously described [36]. Red (FL2) fluorescence of PI-stained cells was measured, and
4 percentage of hypodiploid, apoptotic cells (sub-G compartment of the cell cycle) was determined.
5 Alternatively, apoptotic cell death was assessed after double staining with annexinV-FITC and
6 PI, according to manufacturer's instructions (BD, Heidelberg, Germany). Annexin binds the
7 phosphatidylserine exposed on the membrane of apoptotic cells, while PI labels the DNA in cells
8 with membrane damage. The green (FL1) and red (FL2) fluorescence of annexinV-FITC/PI
9 labeled cells was analyzed, and annexin⁺/PI⁻ and annexin⁺/PI⁺ cells were considered as early and
10 late apoptotic cells, respectively. Flow cytometry analyses were conducted on FACSCalibur flow
11 cytometer using CellQuest Pro software (BD, Heidelberg, Germany).

12 13 *Determination of oxidative stress and mitochondrial membrane potential*

14 Intracellular production of reactive oxygen species (ROS) was determined using redox-sensitive
15 fluorescent dye dihydrorhodamine 123 (DHR; Invitrogen, Paisley, UK). DHR (5 μM) was added
16 to cell cultures at the beginning of the treatment. The mean intensity of green (FL1) fluorescence
17 corresponding to oxidative stress was determined using FACSCalibur flow cytometer.
18 Mitochondrial membrane potential was determined using DePsipher (R&D Systems), a lipophilic
19 cation that has the property of aggregating upon membrane polarization forming an orange-red
20 fluorescent compound. If the potential is disturbed the dye remains or reverts to its green
21 monomeric form. The cells were stained with DePsipher as described by the manufacturer and
22 fluorescence was detected by flow cytometry. The results are presented as green/red fluorescence
23 ratio (mean FL1/FL2), the increase of which reflects mitochondrial depolarization.
