Cellobiose dehydrogenase (CDH, EC 1.1.99.18) from *Phanerochaete chrysosporium* belongs to a group of oxidoreductases and has the ability to degrade different components of woody plants<sup>1</sup>. CDH is secreted by wood degrading, phytopathogenic and saprotrophic fungi and this widespread appearance implies its important function and makes it an important enzyme for applications in industrial and biotechnological processes, as well as biosensors and biofuel cells<sup>1</sup>. CDH is also used in industry for bleaching cotton and in food industry for lactose detection<sup>2</sup>. CDH is a monomeric enzyme consisting of two domains, a flavin domain containing FAD as a cofactor and a smaller heme b containing cytochrome domain, connected via a flexible linker<sup>3</sup>. The physiological role of CDH is reflected in the degradation of cellulose and lignin in cooperation with other cellulolytic enzymes, because CDH catalyzes the oxidation of cellobiose (Glc -  $\beta$  - 1,4 Glc) and other  $\beta$  - 1,4 - linked disaccharides and oligosaccharides to the corresponding lactones<sup>1,2</sup>. Enzymes used in biosensors and for bleaching cotton should have high stability, especially toward reactive oxygen species. In order to improve the oxidative stability of CDH, we have mutated CDH and tested its stability in the presence of hydrogen peroxide. After successful cloning of the CDH gene in the pYES2 vector, saturation mutagenesis was used to create library mutants where three methionine residues were mutated. The residual activity of the mutants was measured after the enzyme incubation in 0.3 M hydrogen peroxide for 0, 2 and 6 h. After analysis of a large number of mutants, it was observed that three mutants are showing higher oxidative stability compared to the wild-type enzyme. The residual activities of these mutants after 6 h of incubation in the hydrogen peroxide were over 50%, whereas the wild-type has 30%. Selected mutants were expressed in *S. cerevisiae* and purified on a DEAE column. The purity and activity of the enzymes were detected on the electrophoresis gel, the oxidative stability of the purified mutants was measured once again and the characterization of these mutants was completed.

**Figure 1.** Residual activity of library 1 mutants at times of incubation in 0.3 M H<sub>2</sub>O<sub>2</sub>.

**Figure 2.** Residual activity of library 2 mutants at times of incubation in 0.3 M H<sub>2</sub>O<sub>2</sub>.

**Figure 3.** Residual activity of library 3 mutants at times of incubation in 0.3M H<sub>2</sub>O<sub>2</sub>.

Mutants showing increased oxidative stability were sequenced and we have decided to combine these mutations with each other in order to make combined mutants that will be tested for oxidative stability. Screening library mutants for improved features in microtitatar plates is a long time process, in order to shorten the time necessary for screening libraries with 106 mutants we are developing fluorescent assay for flou cytometry.

## **Acknowledgements**

This study was supported by founds from the Ministry of Education and Science, Republic of Serbia by the project number NO46010 and DAAD founding organization. One part of this PhD thesis was done at Fraunhofer institute, RWTH University, Aachen, Germany in collaboration with Prof. Rainer Fischer and Raluca Ostafe.
